**Abstract.** In this extended abstract, we discuss a strengthening of a result of Füredi that every  $n$ -vertex  $K_{r+1}$ -free graph can be made  $r$ -partite by removing at most  $\frac{r-1}{2r}n^2 - e(G)$  edges. In addition, we answer a problem of Sudakov showing that  $K_6$ -free graph can be made bipartite by removing at most  $4n^2/25$  edges. We use flag algebras to express local cuts.

**Keywords:** max cut, Turán graph, flag algebras

## 1 Introduction

Let  $G$  be a graph. Denote by  $\text{del}_r(G)$  the minimum order of a set of edges  $X$  such that  $G - X$  is  $r$ -partite. In this extended abstract we explore the problem when  $G$  is  $K_{r+1}$ -free and we focus on  $\text{del}_r(G)$  and  $\text{del}_2(G)$ . In the first case, Füredi [5] provides an upper bound for  $\text{del}_r(G)$ . Recall that the number of edges in  $K_{r+1}$ -free graph on  $n$  vertices upper bounded by number of edges in  $\frac{r-1}{2r} \cdot n^2$ .

**Theorem 1 (Füredi [5]).** *Fix  $r \geq 2$ . If  $G$  is an  $n$ -vertex  $K_{r+1}$ -free graph, then  $\text{del}_r(G) \leq \frac{r-1}{2r} \cdot n^2 - e(G)$ .*

When the number of edges of  $G$  is close to extremal, Theorem 1 was sharpened in [1,6]. Here we focus on global improvement. We conjecture that Theorem 1 can be strengthened as follows.

*Conjecture 1.* Fix  $r \geq 2$ . If  $G$  is an  $n$ -vertex  $K_{r+1}$ -free graph, then  $\text{del}_r(G) \leq 0.8 \left( \frac{r-1}{2r} \cdot n^2 - e(G) \right)$ .

Conjecture 1 would be best possible if true. We describe constructions showing that 0.8 cannot be improved in Section 3. We prove the conjecture for  $r \in \{2, 3, 4\}$ . As a general step towards Conjecture 1, we show the following improvement of Theorem 1.

**Theorem 2.** *For every  $r \geq 2$  there exists  $\varepsilon := \varepsilon(r) > 0$  such that the following holds. If  $G$  is an  $n$ -vertex  $K_{r+1}$ -free graph, then  $\text{del}_r(G) \leq (1-\varepsilon) \left(\frac{r-1}{2r} \cdot n^2 - e(G)\right)$ .*

Note that  $\varepsilon(r) \rightarrow 0$  as  $r \rightarrow \infty$  while Conjecture 1 claims  $\varepsilon(r) = 0.2$ .

Closely related problem is the following conjecture of Sudakov.

*Conjecture 2 (Sudakov [8]).* Fix  $r \geq 5$ . For every  $K_r$ -free graph  $G$

$$\text{del}_2(G) \leq \begin{cases} \frac{(r-2)^2}{4(r-1)^2} n^2 & r \text{ even, and} \\ \frac{r-3}{4r} n^2 & r \text{ odd.} \end{cases}$$

Sudakov [8] proved the conjecture for  $r = 4$ .

**Theorem 3 (Sudakov [8]).** *If  $G$  is an  $n$ -vertex  $K_4$ -free graph, then  $\text{del}_2(G) \leq n^2/9$ .*

We prove the conjecture for  $r = 6$ .

**Theorem 4.** *If  $G$  is an  $n$ -vertex  $K_6$ -free graph, then  $\text{del}_2(G) \leq 4n^2/25$  edges. Moreover, if  $\text{del}_2(G) \leq 4n^2/25$ , then  $G$  is a Turán graph  $T(n, 5)$ .*

Notice that Conjecture 2 does not cover triangle-free case. The triangle-free case is a conjecture of Erdős [3] stating that every triangle-free graph can be made bipartite by removing at most  $n^2/25$  edges. There is a well know bound that removing  $n^2/18$  edges is enough by Erdős, Faudree, Pach, and Spencer [4]. An improvement using flag algebras in a similar manner as we do in this paper was announced recently by Balogh, Clemen, and Lidický [2].

The previously mentioned theorems and conjectures can be extended from  $K_r$ -free graph asymptotic results for  $H$ -free graphs using the regularity lemma.

We extensively use flag algebras, a versatile tool developed by Razborov [7]. We use convention that unlabeled vertices are depicted as black circles, labeled vertices as yellow squares, edges as blue lines. Dashed lines indicate that both edge and non-edge are admissible. We use  $[\cdot]$  to denote the unlabeled/averaging operator. We omit  $\phi(\cdot)$  at most places to improve readability.

The rest of this extended abstract is organized as follows. We describe an alternative proof of Theorem 1 using flag algebras. This demonstrates how the other proofs are constructed. Then we examine the possible extremal constructions for Conjecture 1 and give the main ideas for proving the next case.

## 2 Theorem 1

As a warm-up to our techniques and arguments, we rephrase the proof to flag algebra language. Suppose Theorem 1 is false, and let  $r$  be the smallest integer for which it fails. Clearly,  $r \geq 3$ . Let  $G$  be an  $n$ -vertex  $K_{r+1}$ -free graph  $G$  such that  $\text{del}_r(G) > \frac{r-1}{2r} \cdot n^2 - e(G)$ . For a vertex  $v \in V(G)$ , consider an  $r$ -partition of  $V(G)$  with  $A_r := V \setminus N(v)$  being one part, and  $(A_1, A_2, \dots, A_{r-1})$  an  $(r-1)$ -partition of the neighborhood  $N(v)$  given by Theorem 1. It follows that the

number of edges inside the parts is at most  $e(G[A_r]) + \text{del}_{r-1}(G[N(v)])$ , which is at most

$$e(G[A_r]) + \frac{r-2}{r-1} \cdot \frac{|N(v)|^2}{2} - e(G[N(v)]). \tag{1}$$

On the other hand, this is at least  $\text{del}_r(G) > \frac{r-1}{2r} \cdot n^2 - e(G)$ . This is in direct contradiction with the following simple flag algebra proposition, which shows that if we choose a vertex  $v$  uniformly at random, then the expectation of (1) is at most  $\frac{r-1}{2r} \cdot n^2 - e(G)$ .

**Proposition 1.** *Fix  $r \geq 2$ . If  $\phi$  is a  $K_{r+1}$ -free limit, then*

$$\phi \left( \left[ \begin{array}{c} \bullet \\ \square \end{array} \bullet + \frac{r-2}{r-1} \times \begin{array}{c} \bullet \\ \bullet \\ \square \end{array} - \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \square \end{array} - \frac{r-1}{r} \times \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \square \end{array} + \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \bullet \\ \square \end{array} \right] \right) \leq 0.$$

*Proof.* We will show that the following identity holds for every  $r > 1$ . It immediately proves the statement since the right hand side is non-negative while  $r - r^2$  is negative.

$$(r - r^2) \cdot \left[ \begin{array}{c} \bullet \\ \square \end{array} \bullet + \frac{r-2}{r-1} \times \begin{array}{c} \bullet \\ \bullet \\ \square \end{array} - \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \square \end{array} - \frac{r-1}{r} \times \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \square \end{array} + \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \bullet \\ \square \end{array} \right] = \left[ \left( (r-1) \times \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \square \end{array} - \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \square \end{array} \right)^2 \right].$$

Firstly, observe that the left-hand side is equal to

$$\left[ (1 - r^2) \begin{array}{c} \bullet \\ \square \end{array} \bullet + \begin{array}{c} \bullet \\ \bullet \\ \square \end{array} + \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \square \end{array} + (r-1)^2 \left( \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \square \end{array} + \begin{array}{c} \bullet \\ \bullet \\ \square \end{array} \right) - (r-1) \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \square \end{array} \right],$$

which averages to

$$(r-1)^2 \times \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \square \end{array} + \frac{(r-1)(r-3)}{3} \times \begin{array}{c} \bullet \\ \bullet \\ \square \end{array} - \frac{2r-3}{3} \times \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \square \end{array} + \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \square \end{array}. \tag{2}$$

On the other hand, the right-hand side of the identity is equal to

$$(r-1)^2 \times \left( \begin{array}{c} \bullet \\ \square \end{array} \bullet + \begin{array}{c} \bullet \\ \bullet \\ \square \end{array} \right) - (r-1) \times \left( \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \square \end{array} + \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \square \end{array} \right) + \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \square \end{array} + \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \square \end{array},$$

which again averages to (2). This finished the proof.  $\square$

The exact statement of Theorem 1 can be obtained from Proposition 1 by a blow-up argument.

By inspecting the proof above, we can quickly observe that the bound in Theorem 1 is tight only when  $G$  is the appropriate Turán graph, i.e., a complete balanced  $r$ -partite graph. Indeed, in this case Theorem 1 does not allow to remove any edge. However, this is rather a technical ‘‘obstacle’’ and Conjecture 1 improves on it.

### 3 Constructions for Conjecture 1

Conjecture 1 is tight for Turán graphs since it does not allow deletion of any edges in that case. For  $r = 3$ , the complete balanced bipartite graph and a balanced blow-up of  $C_5$ . Hence  $C_5$  acts similarly as a complete bipartite graph with respect to Conjecture 1 and this propagated to larger  $r$ .

Given  $r \geq 2$ , a tight construction for Conjecture 1 can be obtained as follows: Let  $H$  be a join of  $a$  copies of  $K_1$  and  $b$  copies of  $C_5$ , where  $a + 2b = r$ . Let  $G$  be a blow-up of  $H$ , such that all vertices corresponding to  $K_1$ s have the weight  $1/r$  and all the vertices corresponding to  $C_5$ s have the weight  $2/(5r)$ . This captures all tight constructions for  $3 \leq r \leq 5$ , see Figure 1.

Fig. 1. Constructions for Conjecture 1 for  $r = 4$  and 5.

#### 3.1 Conjecture 1 for $r = 3$

Let  $N$  the non-edge type. Let  $C$  be the combination of  $N$ -flags that computes the cut  $L := N(u) \cup N(v)$  and  $R := V \setminus L$ .

Let  $O := \overline{K_3^N} \times (C - 0.8(1/2 - d(G)))$ , which in written using flag algebras loos like

$$O := \begin{array}{c} \bullet \\ \square \end{array} \times \left[ \begin{array}{c} \bullet \quad \bullet \\ \square \quad \square \end{array} + \begin{array}{c} \bullet \quad \bullet \\ \square \quad \square \end{array} - 0.8 \left( \frac{1}{2} \times \begin{array}{c} \bullet \quad \bullet \\ \square \quad \square \end{array} - \begin{array}{c} \bullet \quad \bullet \\ \square \quad \square \end{array} \right) \right]$$

Notice that  $\frac{1}{2} - d(G)$  is the density of missing edges to the complete bipar-  
tite graph. Then  $0.8(\frac{1}{2} - d(G))$  is how many edges we are allowed to delete in  
Conjecture 1. In order to prove Conjecture 1, we need to show that  $O$  is not  
positive.

**Theorem 5.** *If  $\phi$  is a  $K_3$ -free limit, then  $\phi([O]) \leq 0$ . Moreover, if  $\phi([O]) = 0$ ,  
then  $\phi^1 \left( \begin{array}{c} \bullet \\ \square \end{array} \right) \in \{0.4, 0.5\}$  almost surely.*

*Proof.* First, let

$$F_1 := \left( \begin{array}{c} \bullet \\ \square \end{array} - \begin{array}{c} \bullet \\ \square \end{array} \right) \times \left( 3 \begin{array}{c} \bullet \\ \square \end{array} - 2 \begin{array}{c} \bullet \\ \square \end{array} \right).$$

Observe that if  $\phi([F_1^2]) = 0$  then  $\phi^1 \left( \begin{array}{c} \bullet \\ \square \end{array} \right) \in \{0.4, 0.5\}$  almost surely.

Next, consider the following two vectors  $X$  and  $Y$  of  $\sigma$ -flags, where  $\sigma$  is the  
one-vertex type and the co-cherry type, respectively.

$$X = \left( \begin{array}{c} \bullet \\ \square \end{array}, \begin{array}{c} \bullet \\ \square \end{array}, \begin{array}{c} \bullet \\ \square \end{array}, \begin{array}{c} \bullet \\ \square \end{array}, \begin{array}{c} \bullet \\ \square \end{array}, \begin{array}{c} \bullet \\ \square \end{array}, \begin{array}{c} \bullet \\ \square \end{array} \right), \quad (3)$$

$$Y = \left( \begin{array}{c} \bullet \\ \square \end{array}, \begin{array}{c} \bullet \\ \square \end{array}, \begin{array}{c} \bullet \\ \square \end{array}, \begin{array}{c} \bullet \\ \square \end{array}, \begin{array}{c} \bullet \\ \square \end{array}, \begin{array}{c} \bullet \\ \square \end{array}, \begin{array}{c} \bullet \\ \square \end{array}, \begin{array}{c} \bullet \\ \square \end{array} \right), \quad (4)$$

and the following 7 linear combinations of flags using  $X$  and  $Y$ :

$$\begin{aligned} F_2 &= X \cdot (6, -9, 0, 0, -6), & F_4 &= Y \cdot (0, 1, -1, 1, -1), & F_6 &= Y \cdot (0, 2, -2, 1, -1), \\ F_3 &= X \cdot (4, 0, -3, -4, 4), & F_5 &= Y \cdot (0, 1, -1, 2, -2), & F_7 &= Y \cdot (6, 1, 1, -4, -4), \\ F_8 &= Y \cdot (2, -2, -2, 1, 1). \end{aligned}$$

Note that using this notation,  $F_1 = X \cdot (2, 2, -5/2, -5/2, 3)$ .

Using a flag algebra calculation, we can express each term as a linear combi-  
nation of 5-vertex unlabeled flags and obtain

$$\begin{aligned} -5065 [O] &\geq \frac{554}{5} [F_1^2] + \frac{133}{10} [F_2^2] + 69 [F_3^2] + \frac{2471}{2} [F_4^2] + \frac{7627}{4} [F_5^2] \\ &\quad + \frac{2771}{2} [F_6^2] + \frac{287}{4} [F_7^2] + 114 [F_8^2] \geq 0. \end{aligned}$$

Therefore,  $\phi(\llbracket O \rrbracket) \leq 0$ . Moreover, if the equality is attained for  $\phi$  then  $\phi(\llbracket F_i^2 \rrbracket) = 0$  for all  $i \in [8]$ , and, in particular,  $\phi^1 \left( \begin{array}{c} \bullet \\ \diagup \quad \diagdown \\ \square \end{array} \right) \in \{0.4, 0.5\}$  almost surely.  $\square$

By standard blow-up arguments, we deduce from Theorem 5 that Conjecture 1 holds for  $K_3$ -free graphs.

## 4 Concluding Remarks

Similar approach to Conjecture 1 as for  $r = 3$  works also for  $r = 4$  and  $r = 5$ . Although more ways if finding the partition are more squares are needed in the proof. Here the complexity of the proof grows with  $r$  since we need to find good partition of an increasing number of tight constructions. It is not obvious how to generalize this approach to all  $r$ . However it is possible to obtain an improvement over Theorem 1.

Theorem 4 works along similar lines.
